Hybrid Quantum-Classical Operating Systems (HQCOS) For Embedded Devices

Masia Wisdom
Department of Electrical Engineering & Computer Science, Howard University
IBM-HBCU Quantum Center

Motivation & Project Aims

Rapid advancements in quantum computing have opened a new world of possibilities in the realms of computational power and efficiency. These advancements promise new solutions to complex problems that traditional classical computers either take an unrealistic amount of time to solve or can't solve altogether. Despite these promises, quantum computers are not yet feasible in every day life due to their extreme operating conditions, error rates, and limited qubit capacity. Synonymously, embedded systems which are an integral part of numerous industries such as automotive, healthcare, and consumer electronics are continuing to grow in its market size with its projected growth of up to 1.4 trillion by 2026. These paradigms present a unique opportunity: to bridge these gaps between classical and quantum computing processes and usage. By integrating quantum processes into classical embedded systems, we will be able to enhance performance and efficiency preparing us for the future where quantum computing is mainstream.

Literature Review

Investigating the current state of quantum computing, embedded systems, computer architecture, and other hybrid computing processes & systems will be essential to this research of a hybrid classical-quantum OS for embedded devices. Identifying specific gaps and challenges already faced by current researchers will help drastically to solve problems of today. "Quantum-Classical Hybrid systems and Ehrenfests theorem" by Alessandro Sergi discusses the extending Ehrenfests theorem to quantum-classical application. "Embedded Systems Education: experience with application-driven pedagogy" discusses the urgency to equip the next generation of embedded systems engineers with the necessary skills for development.

Methodology

Researching a process of this sort requires an in depth methodology as any type of operating system encompasses multiple complex parts working together to achieve either one function (specific system) or multi function (traditional OS, i.e windows)

- Requirement Analysis: define function/nonfunctional requirements of the systems process
- System Design: create an architectural design for the hybrid operating system
- Development & Implementation: develop the HQCOS prototype based upon design specs
- Simulation & Testing: validate functionality and performance of HQCOS
- Optimization & Refinement: Optimize this system for better performance and reliability

Given this methodology, definement and scope of the Quantum-Classical OS for E. Achieving tangible results are very much possible.

Future Results & Processes In Practical Application

Hybrid Quantum-Classical Operating Systems (HQCOS)
Will leverage quantum & classical computing to enhance data processing, scheduling, tasks in embedded systems, particularly IoT devices.

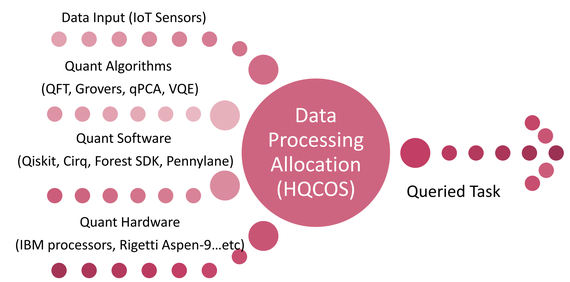

Fig 4. *displays the process of a supposed quant-classical embedded system and how it executes tasks. Beginning from the input sensors algorithms are then executed from inputted data, software controls this execution and hardware processes these instructions all wrapped in a single base OS process (traditional or methodical)*

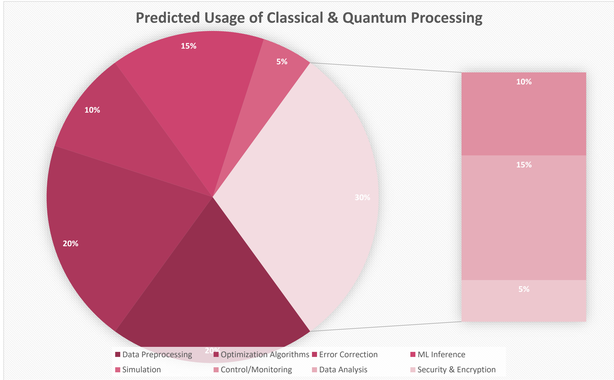

Fig 5. *shows the usage percentage of a quant-classical embedded system and how much resources are allocated to each section of the devices build.*

Real-Time decision-making processes in HQCOS

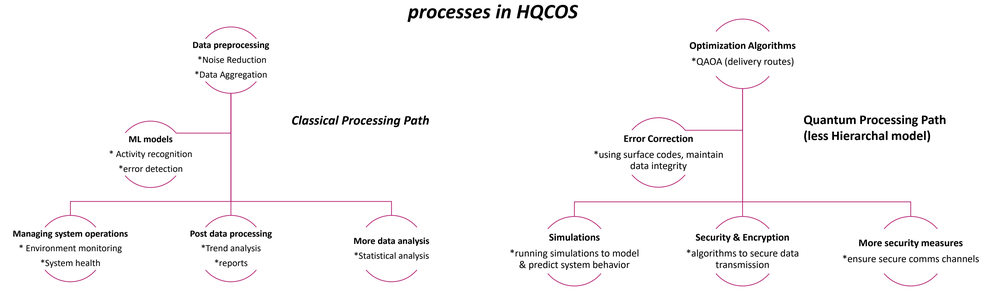

Fig 6 & 7. shows the difference in processing paths for classical (left) and quantum (right), quantum having less of a hierarchal structure as a standalone operation

Fig 8. *shows a few potential impacts of an HQCOS and quantifies its advantages over traditional classical computing and resource management methods*

Potential Impact	Details
Performance Improvement	HQCOS reduces processing time for optimization tasks substantially
Resource Efficiency	Enhanced data processing capabilities lead to faster results in real-time applications and lower energy consumption
Computational Resources	Better resource management minimizes idle times and maximizes throughput reducing need for additional hardware & lowers maintenance

Discussion and Conclusions

This research explores the development and potential impact of a Hybrid Quantum-Classical Operating System (HQCOS) for embedded devices. The primary goal is to integrate quantum processing capabilities into classical computing systems to enhance performance and efficiency as we transition from traditional classical computing devices to more advanced ones. As quantum computing technology advances, the integration of quantum processes into embedded systems becomes increasingly viable, offering significant improvements in several key areas.

Summary of key potential findings include:

•**Performance Improvement**: HQCOS can significantly reduce processing times for complex tasks, leveraging quantum algorithms like QAOA and quantum annealing for optimization and real-time data processing.

•**Resource Efficiency**: By optimizing resource allocation, HQCOS can reduce energy consumption and operational costs. Quantum-enhanced memory management, power management, and network management contribute to more efficient utilization of computational resources.
•**Enhanced Security**: Quantum cryptography can provide intelligent and powerful security solutions, protecting sensitive data and communications in embedded systems.
•**Advanced Error Correction**: Implementing quantum error correction methods can improve the reliability and stability of embedded systems, reducing error rates and maintaining data integrity.

Here are a summary of potential traditional OS components to benefit from these processes:
•**Task Scheduling**: Optimized task scheduling using quantum algorithms.
•**Memory Management**: Improved memory utilization and reduced fragmentation.
•**Data Encryption**: Enhanced security through quantum cryptography.
•**Network Management**: Efficient routing and resource allocation in networked systems.
•**Signal Processing**: Superior performance in filtering, compression, and noise reduction.
•**Real-Time Data Processing**: Faster and more accurate real-time analysis and decision-making.

Below are some of the biggest challenges that engineers,scientist, and researchers such as myself will come across:
•**Technology Maturity**: Quantum computing is still in its very early stages, and the hardware and algorithms required for practical integration are continually evolving.
•**Compatibility**: Ensuring seamless integration between classical and quantum components requires sophisticated interfaces and middleware to perform tests and validation.
•**Resource Management**: Balancing the computational load between classical and quantum processors is complex and requires advanced scheduling and resource management techniques.
•**Cost**: The development and deployment of quantum-capable hardware are currently expensive, which may limit accessibility and widespread adoption in the near term, cutting down these costs are essential.

Future Work

Future work on this research project would consist of focusing on specific parts of computer architecture in embedded systems that would benefit most from quantum input. These include but are not limited to. The percentages reflect average CPU consumption usage.

- Task Scheduling (5-10%)
- Resource Allocation (5-15%)
- Memory management (10-20%)
- Parallel processing (Varies)
- Signal Processing (10-30%)
- Real time data processing (20-40%)
- Network & Power Management (5-20%)

Continued development of hybrid algorithms that leverage both quantum and classical properties will be most practical in the near future. Conducting pilot projects in various industries such as healthcare, finance, and manufacturing will give much useful data into how the peak usage of these processes can be taken advantaged of in modern times. Finally, conducting research on how HQCOS can scale with advancements in quantum science will be most beneficial.

Acknowledgements

Thank you to Howard University department of electrical engineering and computer science for broadening my knowledge and scope enabling to realize great findings and possibilities such as this research. A huge thank you to IBM HBCU Quanum for allowing people like me to be apart of such a magnificent time in science history were quantum information and sciences are very near everyday practical usage. Lastly, very big thank you to Harvard University & Quantum Noir for allowing me to represent my HBCU & myself on their wonderful campus at this time.
